Abstract
There is now sufficient evidence on the actual and potential adverse health effects of radio frequency (RF)
devices like mobile phones and Wi-Fi to require the application of the Precautionary Approach to the
management of the health risks.

In 2011, the International Agency for Research on Cancer (IARC, a WHO agency) classified radiofrequency
electromagnetic fields as a possible human carcinogen.

The Precautionary Approach is enshrined in various pieces of Australian legislation from public health to
fisheries; however, it is yet to be applied in national approaches to radiation.

The Precautionary Approach can provide a means of moving forward in the face of uncertainty, reducing the
risk of possible adverse health effects and promoting research to better understand these health effects. The
“ALARA” principle can be considered a historical version of the Precautionary Approach.

This paper examines the evidence for health effects and how the Precautionary Approach can be implemented
and discusses the wider issues around its use.

Key Words
Electromagnetic Radiation, EMR, EME, EMF, RF, Microwaves, Wi-Fi, Mobile Phones, Health, Cancer,
Precautionary Approach.
1. The difference between the Precautionary Principle and Approach

The terms “Precautionary Approach” and “Precautionary Principle” are often used interchangeably, but there is a difference [1]. In legal terms, a principle (of law) is a fundamental statement and binding. There is some hesitation in using the term “principle” to guide the management of risk when there are scientific uncertainties. The concept of “approach” is more flexible and implies a way of focussing on risks in a prudent manner. In international law, the terms are often interchanged [2] but there are subtle differences, which are discussed below. The term “Precautionary Approach” rather than “Precautionary Principle” will be used, as the effective differences are small.

These concepts were explored in an unpublished White Paper [3] by one of us (DB) for SafeWork Australia, to facilitate a move towards adopting the Precautionary Approach to extend the “Code of Practice on Risk Management” in workplaces [4], when there was scientific uncertainly about the risk.

1.1. The concept of precaution

The concept of precaution is reflected in sayings like “an ounce of prevention is worth a pound of cure” and “look before you leap”. It is countered by other sayings like “nothing ventured, nothing gained”, and “he who hesitates is lost”.

The principal shift in the management of risk in the face of uncertainty is the change from asking "what level of harm is acceptable?" to a precautionary approach which asks, "how can we prevent harm?”. It is also a shift from “damage control” and “polluter pays” to “pre-damage control” or prevention [5].

1.2. Precautionary Principle

There are various forms of the definition of the Precautionary Principle internationally, which can be classified as weak, moderate or strong, depending on the degree of onus on the regulator to act and whether there is a reversal of the “burden of proof” [5].

- **The weak version** is the least restrictive and allows preventive measures to be taken in the face of uncertainty, but does not require them. The 1992 Rio Declaration is an example of the “weak” version. Many “weak” versions explicitly consider the cost-effectiveness of precautionary measures.
- In **moderate versions** of the principle, the presence of an uncertain threat is a positive basis for action, once it has been established that a sufficiently serious threat exists.
- The **strong versions** of the principle differs from the weak and moderate versions in reversing the burden of proof and in reponsibilty for paying the cost.

For a significant health hazard, the creators of the hazard could be expected to accept most of the cost in adopting the Precautionary Approach, particularly where large populations are involved.

1.3. Precautionary Approach

A simple and general definition of the Precautionary Approach could be “A risk management framework in the face of scientific uncertainty”.

However, the successful implementation of the Precautionary Approach is complex and requires widespread trust in the process to make it workable and acceptable. The approach has to be seen to be fair and reasonable. For this to be evident, a high degree of transparency and openness is required. Use of the Precautionary Approach is effectively a social license to continue business in the face of the uncertainty of a known risk.

1.4. ALARA and ALARP

As Low As Reasonable Achievable (ALARA) and As Low As Reasonable Practicable (ALARP) are historical Precautionary Approaches, but lack the same formal structures that surround the comprehensive implementation of the Precautionary Approach.

The ALARP principle was used in the UK Health and Safety at Work etc. Act 1974 and required the “Provision and maintenance of plant and systems of work that are, so far as is reasonably practicable, safe and without risks to health”. The meaning of “reasonably practicable” has been the subject of UK case law since 1949.
must be averted unless there is a large imbalance between the costs and benefits of doing so. ALARA is widely used with ionizing radiation.

1.5. Trigger Points
The trigger points for invoking the Precautionary Principle can be variable depending on the perceived or likelihood of risk [6]. There are two main factors that trigger the precautionary approach. These are:

- the strength of evidence and
- the potential cost of doing nothing.

As in the case of many toxic agents, the delay between disease and full biological explanation can occur over many decades; for example:

- Asbestos (1898-1999): 101 years
- Water contaminated with cholera, Dr John Snow (1854 – 1883): 29 years

2. Current Australian EMF- RF Regulation
The Australian Communications Media Authority (ACMA) is the radio communications regulator. The Radiocommunications Act 1992 Section 162 (3) (f) [7] imposes upon ACMA the regulatory responsibility to provide health and safety protection to persons who operate, work with or use wireless equipment via the establishment of standards.

Currently, the ACMA collects revenue on behalf of the Australian Government through broadcasting, radiocommunications and telecommunications taxes, charges and licence fees. It also collects revenue from price-based allocation of the RF spectrum. When government health and safety protection responsibilities are considered, there are obvious conflicts of interest in those roles.

Another major problem which is often overlooked is that when ACMA chose subsections of the ARPANSA RPS3 (based on ICNIRP 1998 RF Guidelines) as the “standard” to provide health and safety protection, it specifically excluded 5.7 (e) covering precautionary measures because “(i) inclusion of the precautionary principle in the ACMA regulatory instruments would place a regulatory burden on industry which would require strong justification. The ACMA does not discern that justification.”

3. The evidence for health effects of EMF-RF
The current ICNIRP Guidelines were developed in 1998, well before the explosion in mobile phone use. The guidelines are largely based on thermal effects. Non-thermal effects are effectively ignored, because in 1998 there was no substantiated evidence of health effects on humans.

The ICNIRP 2002 statement [8] under “People being protected” notes that:

“Different groups in a population may have differences in their ability to tolerate a particular NIR exposure. For example, children, the elderly, and some chronically ill people might have a lower tolerance for one or more forms of NIR exposure than the rest of the population.”

However, ICNIRP has made no attempt to take a Precautionary Approach for these at-risk groups, instead placing the onus of responsibility on “relevant authorities in each country”.

The ARPANSA Review TR-164 for the period 2000-2012 has been determined to be a flawed document. The authors not only failed to use the available evidence in their own database but they completely ignored the overwhelming evidence in the scientific literature associated with oxidative stress effects [9].

The supposition in TR-164 that microwave radiofrequency transmissions cannot cause cancer is flawed. It is argued that a photon of this wavelength does not have enough energy to directly break ionic bonds like an X-ray, and therefore could not possibly cause damage or mutations in DNA. This simplistic approach sounds like good physics, but it isn’t good biology. Ionising radiation is only one way of causing the mutations in DNA which can produce cancer. Another common pathway shared by all causes is that they produce an inflammatory
response in the body which increases the activity of free radicals (reactive oxygen species or ROS). These free radicals produce oxidative damage in the tissues [10].

3.1. **Evidence ORSAA Database - Human epidemiological studies**

The ORSAA database contains 252 epidemiological studies that are specific to mobile phones as shown in Figure 1. Some of these studies are country specific, while others are international studies. Other smaller studies are often occupationally based. These studies have been conducted to explore the relationship between mobile phones and health.

One of the problems with studies that have demonstrated an association is that use of cumulative hours is a crude measure of exposure, because while a mobile phone user may have a low number of annual hours, they still may have had large exposure because of poor signal strength.

Other flaws with mobile phone epidemiology are [11]:

1. Selection bias
2. Recall bias
3. Insufficient latency time
4. Definition of “regular” cellphone user
5. Inclusion of business users with controls
6. Inclusion of cordless phone users with controls
7. Exclusion of young adults and children
8. Brain tumour risk from cell phones radiating higher power levels in rural areas not investigated
9. Exposure to other transmitting sources are not considered
10. Exclusion of brain tumour types
11. Tumours outside the cellphone’s radiation plume are treated as exposed
12. Exclusion of brain tumour cases because of death or participants too ill to respond

Despite all these flaws, some flaws diluting the ability of studies to detect significant effects, there are studies which do show a positive statistical association between cumulative hours used and certain rare nerve tumours found in the brain and ear. Figure 1 shows the analysis of all 252 epidemiological studies in the ORSAA database.

![Figure 1: Summary of the evidence for UHF studies](image)

In the INTERPHONE study (2000-2004) [12] some 6100 cancer patients were interviewed. These patients had rare nerve sheath tumour types (Acoustic Neurinoma), as well as brain tumour types Glioma and Meningioma as summarized in Table 1.
Table 1 Summary of Interphone and Patient’s studied

<table>
<thead>
<tr>
<th>Patients interviewed</th>

</tr>
</tbody>
</table>

The Interphone study showed an increase in the risk of glioma in the group with the longest duration of use (≥1640 h) (OR=1.40; 95% CI 1.03 to 1.89), higher for ipsilateral use and temporal tumours. This association was not observed for meningiomas (OR=1.15; 95% CI 0.81 to 1.62) [12].

A multi-centre case-control study by French scientists called CERENAT [13] was a carried out in four areas in France in 2004–2006. Data about mobile phone use was collected through a detailed questionnaire delivered face-to-face. No association with brain tumours was observed for casual mobile phone use. However, a statistically significant association was found in the heaviest users. In these users, time since first use was mostly 5–9 years (49%) or 10 years and more (40%), corresponding to approximately 54 min/day.

Another possible source of bias with epidemiological studies relates to when mobile phone use is measured via self-reporting. However, the COSMOS study [14] investigated the validity of self-reported mobile phone use and found a (surprising) reasonable agreement between self reported use and the actual hours of use as obtained from the mobile phone operators.

Interestingly in the COSMOS study, a number of questions on health effects revealed that 14% reported experiencing symptoms around using a mobile phone and 59% reported some level of concern about mobile phones and health (ranging from 36% showing a little concern, up to 1% showing extreme concern).

3.2. Bradford Hill system of causation

Within the ORSAA database we have incorporated Bradford Hill’s “nine indexes of causation” [15]. Hill’s criteria (i.e. indices) for causation are a group of minimal conditions necessary to provide adequate evidence of a causal relationship between an incidence and a possible consequence. For EMF, the Bradford Hill index “Analogy” is not applicable and is thus omitted. For each epidemiological study in the database, the number of Hill indices that are satisfied within that particular paper are noted. With the ability to compile reports, the ORSAA database provides a summary of the most frequently noted indices (Error! Reference source not found.). Of the eight indices used, four are regularly present within the epidemiology studies; e.g., plausibility.
This application of the Bradford Hill system of causation has not previously been incorporated in this manner to assist in determining whether causation is likely.

3.3. Recognition of causation

Recognition of the possibility of causation between RF-EMF and health effects occurred in May 2011 when the WHO’s International Agency for Research on Cancer (IARC) classified RF-EMR as a **Group 2B possible human carcinogen** [16].

Some researchers [17] believe that the evidence for glioma and acoustic neuroma (Vestibular Schwannoma) being caused by RF-EMF emissions from wireless phone is strong. Furthermore, according to the IARC Preamble [16], the classification should be upgraded to Group 1, i.e., “the agent is carcinogenic to humans”. A revision of the current guidelines for RF-EMF exposure is needed.

3.4. *In vivo* human UHF studies

The *in vivo* studies in both the ORSAA and ARPANSA databases are predominantly animal studies, a very limited number of human studies, such as EEG or ECG monitoring of human female volunteers (foetal and neonatal exposure) and some blood or saliva testing from provocation studies.

Table 2 below summarises the effects shown by such studies, as reported by the ORSAA database.

3.5. *In vivo* animal UHF studies

The bio-effects animal studies for those with Specific Absorption Rate (SAR) exposures ≤ 2 W/kg show that 70% of all studies are “Effect” studies and far outweigh the “No Effect” studies (Figure 3). Furthermore, 3% of the studies are noted as “Effect Positive” studies. The authors of these studies have noted that exposures can lead to potential therapies being available for conditions like reversing Alzheimer’s disease, anti-inflammation protective, adaptive response for cancer treatment, or bone healing.

![Figure 3 In vivo animal studies for ≤ 2 W/kg](image)

Bio-effects data from *in vivo* animal experiments using exposures below the “member of the public” exposure limit (≤ SAR 2 W/kg) reveal some interesting patterns in the bio-effects. For example, in Table 3, the bio-effect “DNA damage” for short-term experiments is rank sixth while for longer-term studies the bio-effect “DNA damage” moves up the ranking of effects. Unfortunately, most of the experiments are short-term and this trend would need more detail investigation.

### 3.6. *In vivo* long-term animal UHF studies

The US Food and Drug Administration (FDA) nominated the need for toxicology and carcinogenicity testing of cell phone Radio Frequency Radiation (RFR) emissions in 1999. At that time, animal experiments were deemed crucial, because meaningful human exposure data from epidemiological studies were not available. A decade later this work was commissioned by the US National Toxicology Program (NTP), an inter-agency program run by the US Department of Health and Human Services to coordinate, evaluate, and report on toxicology within public agencies. The NTP is headquartered at the US National Institute of Environmental Health Sciences (NIEHS).

The NPT study was a 2-year study on rats and mice [18] and the most comprehensive study conducted on the long term health risks of wireless technology, using the following design characteristics:

- Double the usual number of animals required for this type of study,
- Three exposure groups: 1.5 W/kg, 3W/kg, and 6 W/kg,
- Exposure intensity at low non-thermal or non-heating levels,
- Near-field study,
- Three independent panels for determining whether the abnormal tissues were cancerous,
- The NTP solicited unprecedented review from multiple external scientists to critically review all aspects of the data analysis and study findings.

The results of the study were extensively interpreted as follows:
Evidence of Carcinogenic activity was rated as:
1) Clear evidence
2) Some evidence
3) Equivocal evidence of carcinogenic (demonstrated by studies that are interpreted as showing a marginal increase of neoplasms which may be test agent related)
4) No evidence
5) Inadequate study.

Exposure to GSM- or CDMA-modulated cell phone RFR at 1,900 MHz did not increase the incidence of any non-neoplastic lesions in male or female B6C3F1/N mice.

Rat exposures resulted in different outcomes for males and females. Some occurrences of rare nerve sheath tumours were statistically significant and others were not. However, rare nerve tumours, malignant Schwannoma tumours were found in the hearts of male rats. These cell types are also found in the nerves of the human ear. However, these tumours in humans tend to be non-malignant tumours.

Significant positive trends were found for gliomas in male rats exposed to CDMA-modulated RF radiation and for heart schwannomas tumours in male rats exposed to GSM or CDMA-modulated RF.

Malignant gliomas in the brain were present in exposed rats compared to controls; however, this finding was not statistically significant and was thus labelled as equivocal evidence.

A similar far-field animal study has been completed by the Ramazzini Institute in Italy [19]. An interim paper shows the same rare nerve tumours have been found in male rats as in the NPT study. However, these rare nerve tumours were also present in the control male rats, which was not the case in the NPT study. These results are less convincing than the NPT study.

Similar the findings of both studies, gliomas in humans are more common in men than in women [20].

The question is: Does rat research inform human health risk? The answer is it does inform, which is a given in common practice whereby:

- Rats are the preferred animal models for carcinogenicity studies.
- Regulatory agencies currently rely on rodent carcinogenicity bioassay data to predict whether or not a given chemical poses a carcinogenic threat to humans.

4. RF Exposure produces oxidative stress

Chronic inflammation can cause cancer. Cigarette smoke can cause cancer. Toxins and autoimmune disease can cause cancer. One common pathway shared by these causes is that they produce an inflammatory response in the body which increases the activity of free radicals (reactive oxygen species (ROS) /reactive nitrogen species (RNS)). These free radicals produce damage in the tissues.

This oxidative activity is the tool that the human body uses to break down foreign bacteria (DNA fragments etc.) so that it can be digested by the immune system. While free radicals are an important defensive weapon, an excess of oxidative activity can lead to damage of human tissue. Such excesses have been associated with many chronic conditions including autoimmune disease, heart disease, and some forms of cancer. Every week another article is published suggesting that taking antioxidants may be protective against some of these problems.

Though immune cells such as activated phagocytes also produce ROS to kill invading pathogens, which is part of the natural immune defence mechanisms, in environmental toxic exposures it appears that ROS precedes the inflammation (i.e. oxidative stress is the trigger for inflammation). This is further complicated by disruption of the signal transduction pathways, as carefully maintained ROS/RNS are important messengers in keeping the cell's homeostasis. Table 4 below illustrates how the long-term bio-effect of oxidative stress is linked to both cardiovascular disease, neurodegenerative diseases and cancer.

Table 4 below illustrates how the long-term bio-effect of oxidative stress has been linked to both cardiovascular disease, neurodegenerative diseases and cancer [21-24].

5. Conclusions

The evidence that there are health effects from long term exposure to wireless devices like mobile phones is strong. Therefore, using the moderate version of the *burden of proof* described above, further research is needed to clarify the risks. In addition, RF Standards need to be strengthened to provide biological protection against a range of bio-effects noted in well conducted research at a non-thermal level. Radiation protection authorities need to be more forthright with their advice and should be recommending a precautionary approach to government, industry and the general public. For example:

- mobile phones need to be designed to a higher safety standard which considers non-thermal biological effects.
- Stronger recommendations need to be adopted and publicised to ensure safer use by the general public, most especially children and other sensitive individuals.

Currently, it is up to the user to apply a Precautionary Approach to the use of mobile phone and other wireless technology. The awareness of the risk of potential health effects is almost non-existent. Warnings are buried so deep within the mobile phone menus or the phone manuals that no one reads, as is the case with long worded software agreements. Some companies send intermittent SMS messages to targeted users.

As radiation protection scientists we suggest the following: Given the strong evidence for harmful effects reported above, and the possible cost of doing nothing, we believe the **trigger point for adopting a more Precautionary Approach** to this new RF-EMR technology has been reached. We welcome debate and invite responses to this suggestion.
